Abstract

In this paper the author discusses the patients' problem with poly-trauma. In this study we have presented the problems such as: multiple injuries to the body, internal organs and skeletal muscle system. In this writing we observe different accidents and unexpected circumstantial situations, with the medical aids appliances. The aim of this paper is to highlight the role of the nurse in accelerating the first aid when we are far away from specialized centers and rural and urban hospitals. In addition, this paper points out that students and the wide population must be prepared for the first aid to those with poly-trauma and their transportation. It is therefore necessary a professional advancement through various medical training, especially for individuals who work with the first aid before reaching the hospitals. Here, it is noted that all operators involved in trauma emergencies outside the hospitals, in different levels and positions, must have a minimum standard of theoretical knowledge and technical competence, which allows them to provide primary care training and identification of the dynamic clinical situations that require intervention from an experienced team.

Key words: *barrels, bleeding, care, emergency, trauma*
